³ Pacific Southwest Station, Placerville, CA

Genetic survey of Great Basin restoration species

RMRS Shrub Lab, National Forest Genetic Electrophoresis Laboratory (NFGEL) and PNW Genetics are working to:

- **Characterize baseline genetic diversity in ~ 20 different Great Basin natives**
 - **Most species understudied and underrepresented in collections and databases**

- **Evaluate genetic differentiation within and among partitions for all species**

- **Determine genetic identity of seed sources used in post-fire revegetation**

Species Included in the Genetic Survey

■ Shrubs

- *Artemesia tridentata*
- *Atriplex canescens*
- *Ericameria (Chrysothamnus) nauseosa*
- *Purshia tridentata*

■ Grasses

- *Bromus carinatus*
- *Hesperostipa (Stipa) comata*
- *Achnatherum (Oryzopsis) hymenoides*

2001 – 2004 collections

- ≥ 5 populations
- < 5 populations

■ Legumes/Forbs

- *Astragalus utahensis*
- *Balsamorhiza sagittata*
- *Crepis acuminata*
- *Erigeron pumilus*
- *Eriogonum umbellatum*
- *Heliomeris (Viguiera) multiflora*
- *Lupinus argenteus/sericeus*
- *Vicia americana*
- *Ceratoides lanata*
- *Lomatium grayi/dissectum*
- *Penstemon deustus*
- *Phlox longifolia*

Cellular genomes and their properties

■ Nuclear Genome -

- Chromosomes = 2 (diploid) or more (polyploid) per cell
- Biparental inheritance
- Survey using protein polymorphism (allozymes) DNA methods (AFLP)

■ Organellar Genomes –

- Circular haploid chromosome
- Uniparental (maternal) inheritance
- Survey either cpDNA or mtDNA (effectively linked via single parent transmission)

Why study both genomes?

- **Potential to reveal different patterns of diversity**
 - Nuclear loci di- to polyploid, biparental inheritance; organelle genomes haploid, seed transmitted*
 - Alone: heterozygosity, rate of inbreeding, size of maternal neighborhood, gene flow from seed; Combined, gene flow via pollen
- **Potential for contrasting differentiation**
 - Independent unlinked partitions; can record different histories
 - N_e of nuclear genes $\sim 4X$ larger than cpDNA; drift and migration influence organellar genes more than nuclear genes.
- **Nucleo-cytoplasmic interactions and fitness consequences**
 - Sterility/fertility often under cytoplasmic control (e.g., CMS)
 - Alloplasmic replacement: altered disease susceptibility, reduced fitness (maize, wheat)

Genetic Analysis I: Evaluating Variation

Nuclear Variation

- Starch electrophoresis*, AFLP
- 18 enzyme activities screened; up to 28 loci identified (Lupinus)
- Loci/alleles inferred from known patterns in other species (e.g., Wendel and Weeden, 1991)

Organelle Variation

- Length polymorphism in PCR amplified non-coding cpDNA**
- Products fluorescently labeled; multiplex six loci (~3500 bp)
- ID variants in 1 bp intervals
- Code as 'haplotypes'

SOP: www.fs.fed.us/psw/programs/nfgel/publications.shtml

** Horning and Cronn, in review

Genetic Analysis II: Analytical Approaches

■ **Indices of diversity**

- **Allozymes:** % polymorphic loci (P), average alleles per locus (A), expected heterozygosity (H_e)
- **cpDNA:** Total haplotypes, expected heterozygosity (H_e)

■ **Index of differentiation: F_{ST}**

$$F_{ST} = \sigma^2_{\text{AMONG}} / (\sigma^2_{\text{AMONG}} + \sigma^2_{\text{WITHIN}})$$

- Computed using ANOVA (θ), pairwise and across all populations
- Significance evaluated by permutation; contingency tables of alleles x s tested for goodness of fit (G statistic; Goudet et al., 1996).

■ **Test of neutral differentiation: nucleus vs. organelle**

- H_0 : F_{ST} nuclear genes = F_{ST} maternal organelles when N_e included

$$Exp F_{STcp} = 6 \cdot F_{STnuc} / [2 + (4 \cdot F_{STnuc})]$$

- Significance of observed difference tested by bootstrapping approach (Hamilton and Miller, 2002)

Genetic diversity across species examined

<i>Species</i>	Pops	Allozyme			cpDNA	
		%P	A	H _e	N _{Hap} /Pop (N _{Hap})	H _e
<i>Astragalus utahensis</i>	4	63	2.09	0.217	1.25 (5)	0.690
<i>Atriplex canescens</i>	9	61	1.92	0.139	1.67 (15)	0.835
<i>Bromus carinatus</i>	2	19	1.24	0.062	2.0 (4)	0.709
<i>Crepis acuminata</i>	4	58	1.75	0.117	1.0 (5)	0.610
<i>Eriogonum umbellatum</i>	4	67	2.11	0.195	1.25 (5)	0.835
<i>Hesperostipa comata</i>	3	20	1.22	0.078	1.67 (5)	0.685
<i>Lupinus argenteus</i>	7	100	2.8	0.272	1.57 (11)	0.870
<i>Vicia americana</i>	3	54	1.71	0.119	1.0 (3)	0.667

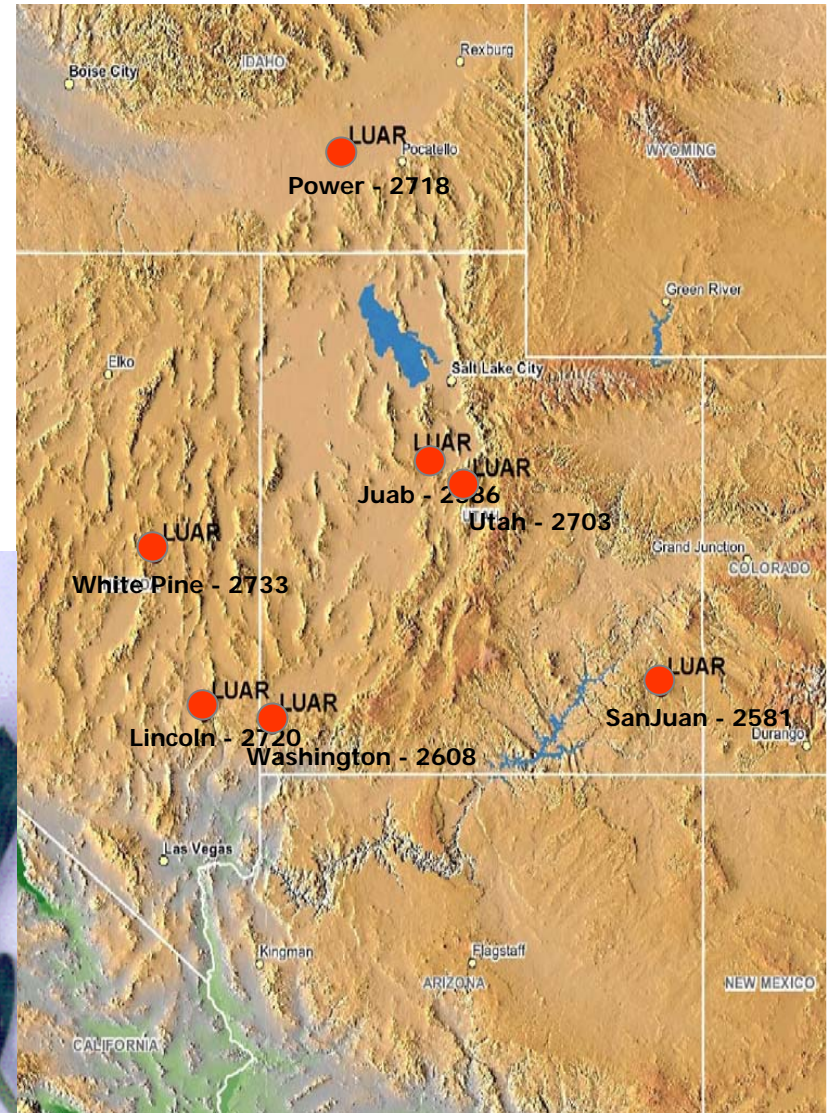

Genetic differentiation across species

<i>Species</i>	Nuclear F_{ST}		cpDNA F_{ST}	cpDNA $F_{ST} (exp)$
<i>Atriplex canescens</i>	0.285	>	0.280	0.545*
<i>Astragalus utahensis</i>	0.357	<	0.394	0.625*
<i>Crepis acuminata</i>	0.276	<	0.580	0.533
<i>Eriogonum umbellatum</i>	0.318	<	0.685	0.583
<i>Bromus carinatus</i>	0.634	<	0.694	0.839
<i>Lupinus argenteus</i>	0.314	<	0.863	0.579*
<i>Hesperostipa comata</i>	0.885	<	0.938	0.916
<i>Vicia americana</i>	0.299	<	0.958	0.561*

Nuclear and cytoplasmic diversity in Lupinus

- *L. argenteus* (and *L. sericeus*?)
- Allozyme diversity at 23 loci, 64 alleles
- cpDNA diversity: 6 loci (3450 bp)
- 7 populations, 20 individuals each
- Mean pairwise distance: 353 km
 - Range: 40 – 640 km)

*Genetic diversity in *Lupinus argenteus**

Population	Allozyme Data			cpDNA Data	
	%P	A	H _e	N _{Hap}	H _e
San Juan UT (2581)	52.2	1.7	0.154	1	0
White Pine NV (2733)	65.2	1.9	0.205	3	0.521
Washington UT (2608)	52.2	1.7	0.144	1	0
Lincoln NV (2720)	91.3	2.3	0.273	1	0
Juab UT (2586)	56.5	1.7	0.169	4	0.678
Power ID (2718)	65.2	2.1	0.255	1	0
Utah UT (2703)	47.8	1.7	0.200	1	0
Population means	100	2.8	0.272	1.7	0.870

*Cytoplasmic differentiation in *Lupinus argenteus**

- **Eleven haplotypes identified**
 - One shared among populations: population 2581 (freq = 1.0) and population 2733 (freq = 0.26)

*Cytoplasmic differentiation in *Lupinus argenteus**

- **Eleven haplotypes identified**
 - One shared among populations:
population 2581 (freq = 1.0) and
population 2733 (freq = 0.26)
- **Five of seven populations fixed for unique haplotype**
 - 1 haplotype: $H_e = 0.0$
 - Fixation occurs in proximal populations (e.g., 2720 vs. 2608)

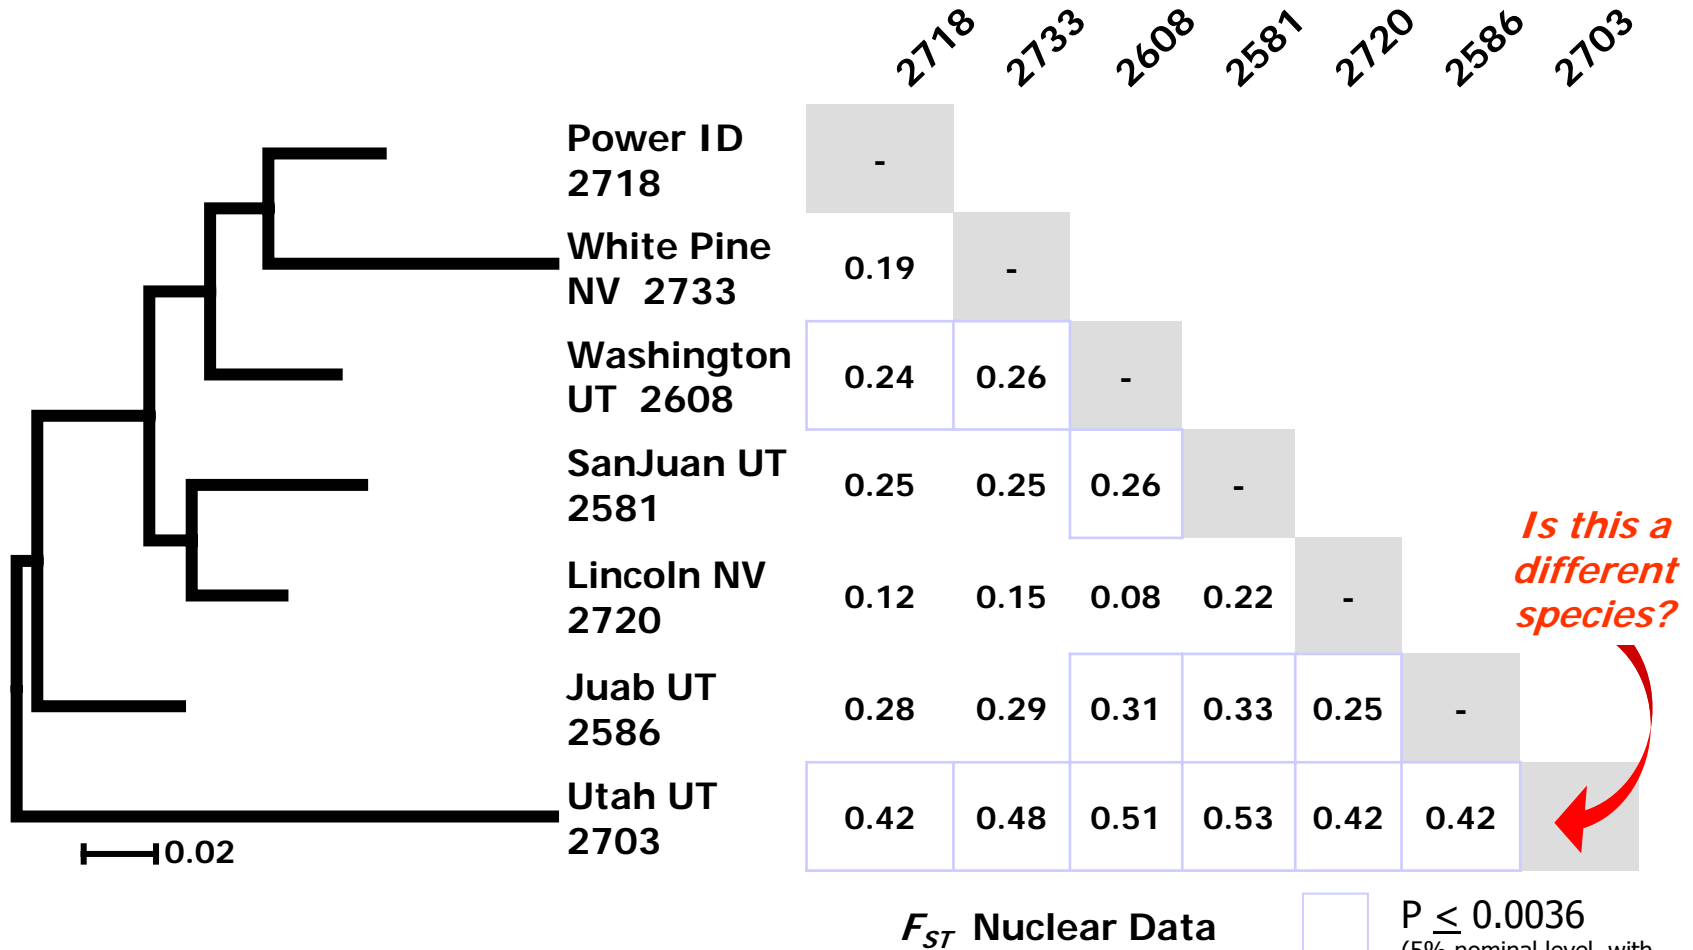

*Cytoplasmic differentiation in *Lupinus argenteus**

- **Eleven haplotypes identified**
 - One shared among populations: population 2581 (freq = 1.0) and population 2733 (freq = 0.26)
- **Five of seven populations fixed for unique haplotype**
 - 1 haplotype: $H_e = 0.0$
 - Fixation occurs in proximal populations (e.g., 2720 vs. 2608)
- **Two populations showed high diversity**
 - 2733: 3 haplotypes, $H_e = 0.521$
 - 2586: 4 haplotypes, $H_e = 0.671$

Nuclear differentiation in *Lupinus argenteus*

NJ phenogram based on Nei's genetic distances

Cytoplasmic differentiation in *Lupinus argenteus*

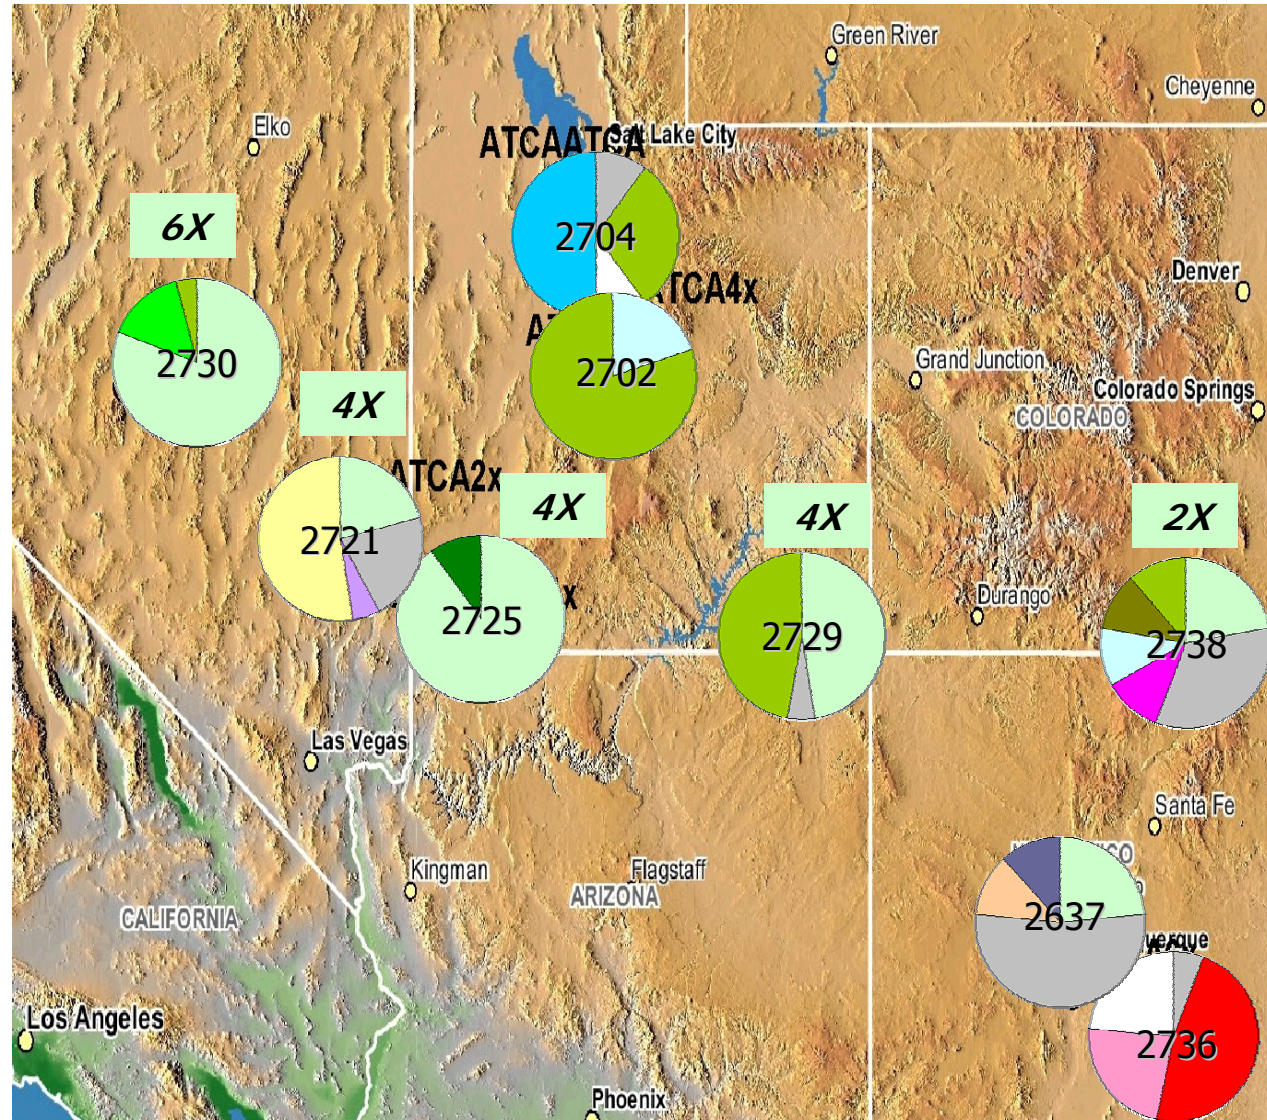

$P \leq 0.0036$
 (5% nominal level, with sequential Bonferroni correction for multiple tests)

Cytoplasmic differentiation significant among sources showing non-significant allozyme differentiation

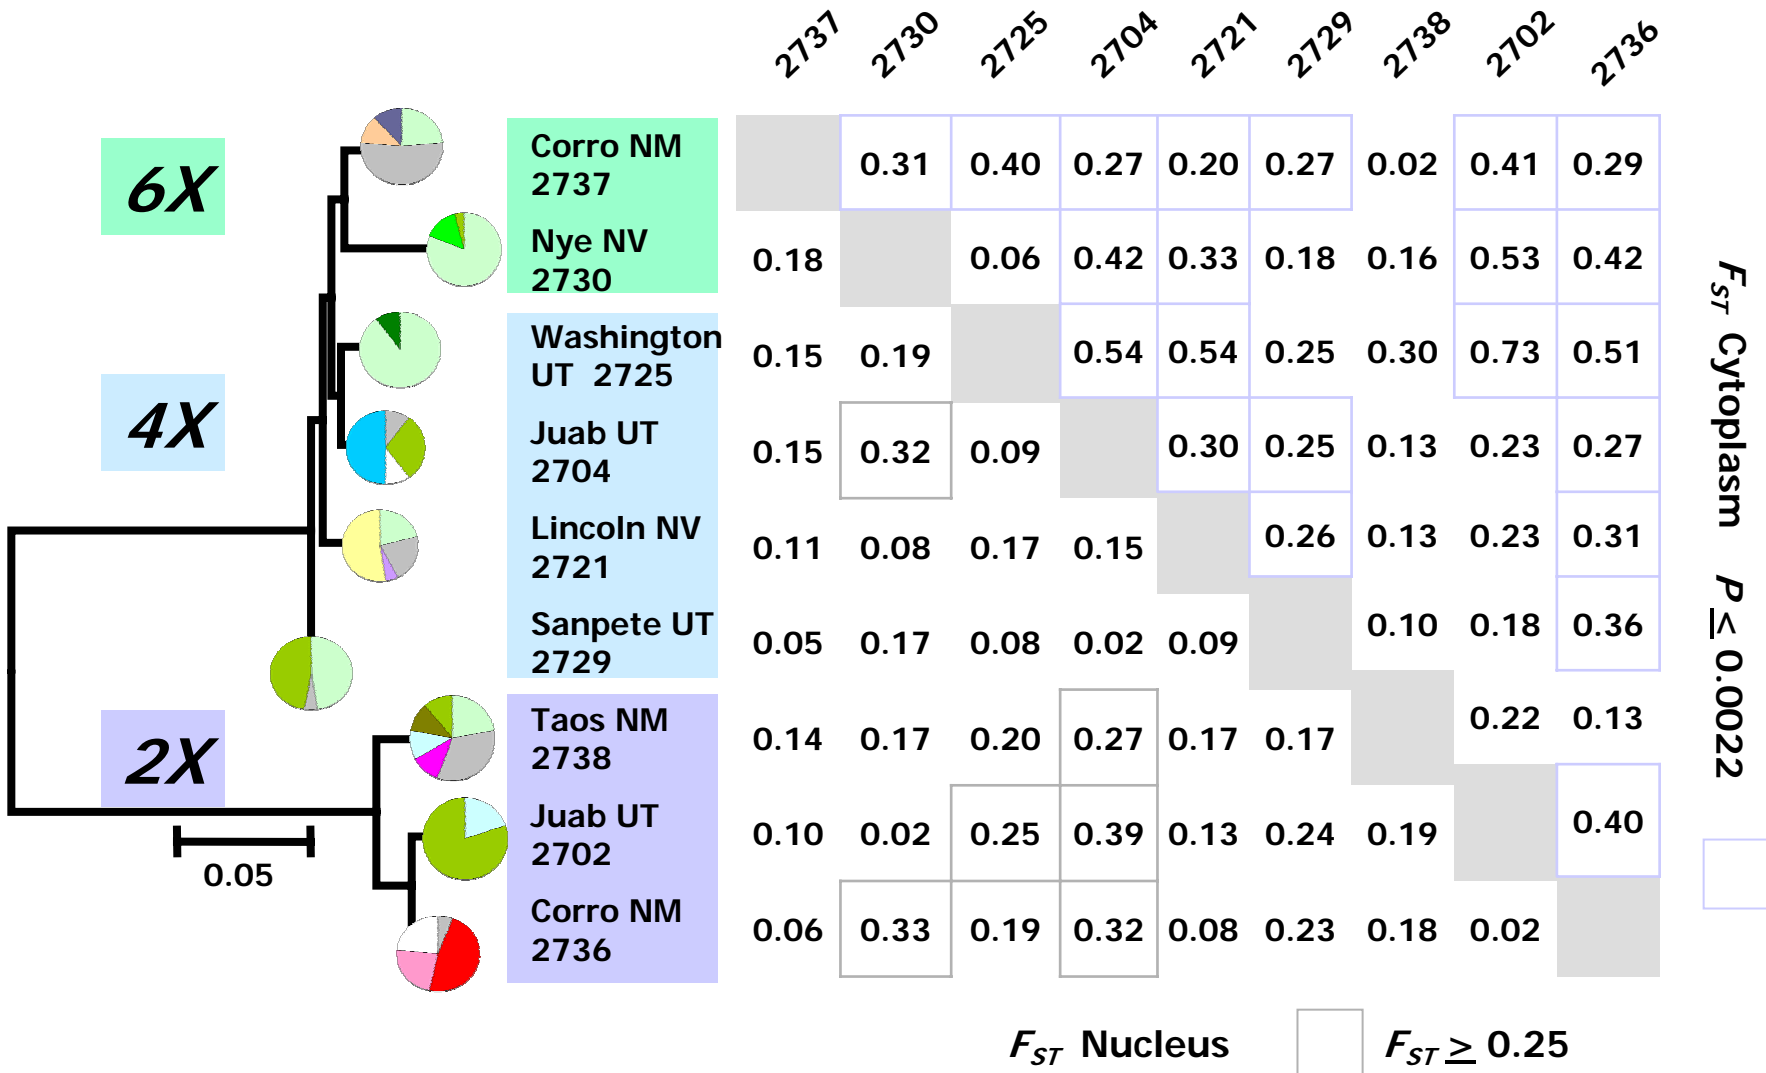

Cytoplasmic differentiation in *Atriplex canescens*

- **Outstanding cpDNA diversity relative to other species**
 - 15 haplotypes across 9 wild populations
 - 4.1 haplotypes per population (N = 20)
- **Low differentiation across populations**
 - Two haplotypes common across study
- **Haplotypes shared across ploidy levels**

Genetic differentiation in *Atriplex canescens*

Summary of findings from the survey

- **Nucleus and cytoplasm differ in magnitude, pattern of genetic diversity**
 - Plants with low nuclear diversity may show abundant cytoplasmic diversity (and vice-versa)
 - Non-significant nuclear differentiation and significant cytoplasmic differentiation can be seen in same plants

*Important for germplasm evaluation, characterization –
cpDNA may provide a region-specific marker*

- **Cytoplasmic differentiation >> nuclear differentiation***
 - In most cases, difference accounted for by smaller N_e of cpDNA
 - Atriplex and Lupine are striking exceptions! Why is $F_{ST_{cp}}$ so low/high?
...unusual seed movement... biparental cp transmission... selection...

*Important for considering the geographic scale
of non-neutral adaptive traits*

Remaining questions, analyses, ideas...

- How consistent are these trends?
 - More populations, species being added
- What is the pattern/magnitude of diversity in seeded populations? What can we say about the apparent rate of seed diffusion? Of pollen flow?
 - Case studies for *Artemesia*, *Atriplex*, *Purshia*
- How frequently are misidentified materials used in restoration?
 - Unusual genotypes present at a measurable frequency
 - Critical need for a reference database that integrates taxonomic and genetic information
- (your good ideas go here _____)
